ABSTRACT
INTRODUCTION: Chronic Obstructive Pulmonary Disease (COPD) is a chronic inflammatory disease due to smoking. It is inevitable as well as treatable. The COPD is a one of the leading cause of morbidity and mortality affecting globally. OBJECTIVE: To evaluate the Frequency of anemia in chronic obstructive pulmonary disease patients in tertiary care hospital Karachi. burden of anemia in chronic obstructive pulmonary disease patients at a tertiary care hospital Karachi. METHODS: This is a descriptive cross sectional study, done at JPMC Karachi in 2014. All COPD patients admitted in medicine and pulmonology departments were enrolled in this study. After informed consent, data of complete blood count was accessed from medical record and anemia was labeled as per operational definition. Data analyzed by SPSS version 16.0. Frequency and percentage proportion of qualitative variables, mean and standard deviation of numerical values were calculated with significant values (P- value <0.05).

RESULTS: Of 137 cases, 118(86.13%) were males and 19(13.87%) were females while gender based ratio was 6.2: 1. The average age (58.31±12.17 years), average weight (59.36±10.56kg), average duration of disease (5.69±4.42 years) and average hemoglobin (12.34±1.58 mg/dl) of the patients respectively. The 37.96% (52/137) patients were anemic in our study. Rate of anemia in COPD patients was not significant among age groups (p=0.076) and with duration of disease (p=0.22).

CONCLUSION: The Anemia is

INTRODUCTION:
The Chronic Obstructive airway or pulmonary disease (COPD or COAD) is progressive inflammatory airway disease that is related to poor quality of life (QOL). The COPD is one of the leading illness causing mortality worldwide. It includes previously two disease processes that are emphysema and chronic bronchitis. It manifests as a chronic breathing problem and poor airflow with air trapping in lungs. According to recommendation of the Global Initiative for chronic obstructive lung Disease (GOLD), that the chronic obstructive airway disease (COAD) or chronic obstructive pulmonary disease (COPD) will be diagnosed on the basis of clinical features (signs and symptoms) i-e productive cough (cough with sputum) for at least 3 months/year for at least two years are characteristic of chronic bronchitis and shortness of breathing or dyspnea and cough are characteristic of emphysema. These disease processes are measured by Spirometry. On the basis of Spirometry COPD patients were staged on the basis of severity of symptoms into four stages (I, II, III & IV) depends upon the FEV1 levels - I (FEV1<30%),II (20%≤FEV1<50%), III (30%≤FEV1<80%) & IV (FEV1≥80 %). These symptoms are chronic, and with passage of time these symptoms worsens and patients deteriorate. It is an emerging burden on the global health system as it is quickly up trending to become one of the leading cause of morbidity and mortality. It is not only considered as a cause of healthcare burden but causing enormous economic and social menace throughout the world. COPD (emphysema and chronic bronchitis) had affected about 174.5 million people or 2.4% of population of the world in 2015 and it occurred mostly in people of having age more than 40 years equally in both genders. In 2015, 3.2 million deaths were reported and it was increased from 2.4 million deaths in 1990. It was estimated that more than 90% deaths were occurred in developing countries. Smoking is considered as one of the leading risk factor for development of chronic Obstructive airway or pulmonary disease (COPD or COAD) and the duration of smoking were having linear relationship with it. The number of deaths will rise in developing countries because of higher
rates of smoking especially in old age people. Smoking is a common risk factor in development of many chronic diseases like ischemic heart disease (IHD) or coronary vascular disease (CVD), cardiac failure and bronchogenic carcinoma or carcinoma of lung. COPD (emphysema and chronic bronchitis) often coexists with other co-morbidities in patients like Ischemic heart disease (IHD), Osteoporosis, Skeletal muscle dysfunction (wasting), Depression and blood disorders (anemia) causing a significant impact on prognosis. These co-morbidities had an effect on potentiating the overall morbidities in patients of COPD, so it leads to increased rate of hospitalizations, poor life style, increased expenses of medical care, and eventually death. It is associated with extra-pulmonary manifestations like anemia. Anemia is caused by chronicity of disease or chronicity of illness, systemic inflammatory or oxidative process, although it is “traditionally” associated with secondary polycythemia but practically many patients are found to be anemic. This anemia is known as anemia of chronic disease (ACD). The systemic effects or systemic inflammation had direct effects of the disease with having a relationship with cause-and-effect output. Screening and treatment of these co-morbid conditions i-e Ischemic heart disease (IHD), Osteoporosis, Skeletal muscle dysfunction (wasting), Depression, nutritional disorders (malnutrition) and blood disorders (anemia) had a role in management of COPD. Chronic systemic inflammation had a vital role in the development of extra-pulmonary manifestations of COPD. Anemia worsens dyspnea or shortness of breathing and limit exercise tolerance. The Hemoglobin (Hb%) levels correlated with reduced functional capacity, increased shortness of breathing, reduced exercise tolerance or capacity, reduced or impaired quality of life (QOL), increased or longer stay in hospital with early mortality and morbidity with severe inflammation in COPD patients. There are many cofounders in chronic obstructive pulmonary disease patients like old age, nutritional disorders (malnutrition) and cardiovascular disease (IHD, CCF), and leads to development of anemia. Nutritional disorders or Malnutrition had association development of anemia due to with iron, folic acid or vitamin B12 deficiency. The aim of this descriptive study is to evaluate the Frequency of anemia in chronic obstructive pulmonary disease patients in tertiary care hospital Karachi. Operational definition: Anemia is defined as a decrease in the total number of Red blood cells (RBCs) or decreased concentration of hemoglobin (Hb%) in the blood, hemoglobin levels <13.5 mg/dl in men, while in women hemoglobin levels <12.0 mg/dl were labeled as anemia.

**METHODOLOGY**

This study was a descriptive cross-sectional, which included 137 COPD patients. These COPD patients were admitted in departments of medicine and pulmonology. This study was conducted for six months in 2014 in Jinnah Postgraduate Medical Center Karachi. The size of sample was calculated by formula: 

**Sample Size**\*: \( n = \frac{Nz^2p(1-p)}{d^2} \) 

Numbers of participants were calculated i.e 137 subjects. After taking approval of synopsis from college of physicians and surgeons of Pakistan (CPSP), subjects were enrolled from admitted patients. Diagnosed cases of COPD, of both male and female sex and Age >35 years and <70 years were included. Patients with Co-morbid conditions e.g. heart failure, end stage renal disease, autoimmune disorder {Systemic Lupus Erythematous (SLE), Rheumatoid Arthritis (RA)}, patients taking iron supplements, history of blood transfusion and refusing for consent were excluded. After taking consent from patients, thorough history and physical examination was done. Data was collected on pre-designed proforma. Each patient’s laboratory data of complete blood count (CBC) was seen from medical record and anemia was labeled as per operational definition. Statistical Package for Social Sciences (SPSS) version 16 computer software was used for analyzing the collected data. The descriptive statistics like frequency, percentage (%), proportion were computed for presentation of qualitative variables like gender, smoker, anemia, Diabetes Mellitus (DM), Hypertension (HTN), educational and economic status. Mean and standard deviation (±SD) were given for presentation of numeric variables like age, weight and hemoglobin (Hb %).

Effect modifier like age, gender, duration of disease, smoking status, DM, HTN, weight were controlled through stratifications and Chi-square (2\( \chi \) test) was applied to detect difference between categorical variables with significant (<0.05) and non-significant (>0.05) p-value.

**RESULTS**

137 COPD patients were enrolled and included in this study, out of this 118(86.13%) were males (M) and 19 (13.87%) females (F) while M to F ratio was 6.2:1. In COPD patients, mean age (58.31±12.17 years (median age 60 years)), mean weight (59.36±10.56 kg), mean duration of disease (COPD) (5.69±4.42 years) and mean hemoglobin (Hb %) 12.34±1.58 mg/dl respectively (Table-I). In COPD patients included in our study frequency of anemia, smoking, hypertension and diabetes mellitus was 37.96% (52/137), 100% (137), 6.6% (9/137) and 2.2% (3/137) respectively. (Table-II). In this study anemia in COPD patients has no significant association with age (p>0.076), gender (p>0.36), and duration of the disease (p>0.22) respectively. (Table III).

DISCUSSION
Anemia is one of the extra-pulmonary manifestations in patients having clinical features (signs and symptoms) of Chronic Obstructive airway or pulmonary disease (COPD or COAD). In this study frequency of anemia has been observed in patients was 37.96%, median hemoglobin (Hb%) level was 12.5 gm/dl and gender based comparison showed frequency of anemia was 36.4% (43/118) in males and 47.4% (9/19) in females which is not statistically significant (p>0.36). Similar results are reported in a study which includes 53 patients with median hemoglobin level(12.8 gm/dl) and gender based comparison showed frequency of anemia was 49.4% [41/83] in males and 52.2% [12/23] in females with P-value (P=1.00). This study supports our results. In 2015, study was published in British Medical Journal (BMJ), in which anemia prevalence is in range b/w 33%–44% in COPD patients. Perveen et al. done a hospital-based cross-sectional study in which she founded 18% anemia in Chronic Obstructive airway or pulmonary disease (COPD or COAD). Shorr et al. had done data analysis of Chronic Obstructive airway or pulmonary disease (COPD or COAD) patients retrospectively in which 33% patients were reported anemic. Anemia is directly associated with worsening of clinical features that leads to mortality or death in chronic obstructive airway disease (COPD) patients. It is considered as predictor, which is affecting the prognosis (long term), so that it is causing mortality in exacerbations of admitted patients. During exacerbation of symptoms in COPD patients, leads to increase in concentration of oxidative stress, plasma fibrinogen and serum interleukin (IL-6) levels, so comorbidities increases in patients. The liver produces the C-reactive protein (CRP) in higher concentration due to to interleukin 6(IL-6).

C-reactive protein (CRP) is sensitive marker of inflammation and acts as an acute phase reactant in the body. The anemia had multiple complex mechanisms in COPD patients like systemic inflammation and anemia of chronic disease (ACD). Multiple inflammatory cytokines are responsible for inhibition or having harmful effect in erythropoietic pathway (erythropoiesis) in COPD patients like interleukins (IL-1,IL-6), and tumor necrosis factor (TNF-alpha). The patients having lower levels of hemoglobin (Hb%) concentration or anemia will be associated with poor prognosis in COPD suffers. ACD occurs due to alternation in iron metabolism. There is increased level of hepcidin, and increased inflammatory cytokines or interleukins (IL-1,IL-6), and tumor necrosis factor (TNF-alpha) in Chronic Obstructive airway or pulmonary disease (COPD or COAD) patients. These are regulating iron homeostasis in human body. Functional iron deficiency is related to decreased oxygen concentration in the blood leads to decreased tolerance of exercise and limitation in response to pulmonary rehabilitation. Yuruk et al. had observed in his study that decreased hemoglobin (Hb%) concentrations or anemia was showing a strong association with COPD exacerbations.
association with oxygen saturation within capillaries or microcirculation and after treatment of anemia resulted in improvement of transport capacity of oxygen and oxygen saturation in tissue cells. Anemia is associated with shortness of breathing and it worsens the health related quality of life. Anemia or decreased hemoglobin concentration is major risk factor for repeated admissions (25%) and worsening of dyspnea than non-anemic COPD patients. Dyspnea and easy fatigability are main symptoms of COPD patients and it exerts negative effects on health and quality of life (QOL) of Chronic Obstructive airway or pulmonary disease (COPD or COAD) patients. Hemoglobin correction (whether anemia or polycythemia) in COPD patients may improve QOL and decrease co-morbidity and mortality of these patients.

CONCLUSIONS
Anemia is quite common in our study population and its pathogenesis is poorly studied; so further studies are needed as to evaluate this. Moreover low hemoglobin level can have adverse effects on oxygen saturation and functional capacity of lungs in these patients, and leads to increased morbidity and mortality. Further studies are needed to look up, if treatment of anemia in COPD patients results into better outcomes.

CONFLICT OF INTEREST: None to declare.
ETHICS APPROVAL: From College of Physicians & Surgeons, Pakistan (CPSP), Acceptance number: REU NO: 8813
FUNDING SOURCE: Nil
PATIENT CONSENT: Informed consent taken from the patients or their guardian, if language barrier via translator.

THE LIMITATIONS OF OUR STUDY: Single centre study.

RECOMMENDATIONS: Future studies with more number of patients and effect of anemia correction on COPD should be studied.

ACKNOWLEDGEMENTS: I dedicate this study to my patients who allowed me to publish their data.
